#### **ABSTRACT**

Results of an experimental program to measure the performance of a compressor stator cascade consisting of 20 downd-3 col inches, aspect ratio 2.0 and solidity 1.67 under conditions of varying incidence angle and Reynolds number are reported. Flow quality and blade performance data were obtained using pneumatic probe surveys and surface pressure measurements. Changes in Reynolds number in the range of 500,000 to 770,000 did not measurably affect either flow quality or blade performance. Changes in incidence angle over the range -15 to 10 degrees produced generally well behaved blade performance parameters.

#### **ACKNOWLEDGMENTS**

I would like to express my thanks and appreciation to Dr. R. P. Shreeve, Director, Turbopropulsion Laboratory, for his efforts in making this study a worthwhile and enjoyable learning experience. Special notes of thanks go to Jim Hammer, Kelly Harris, John Morris, Al McGuire and Friedrich Neuhoff for their prompt and efficient assistance. Finally, to my wife, Melissa and son, Michael, thank you for your patience and support during the course of this study.

The second continues and the second continues and the second continues and the second second

#### I. INTRODUCTION

The on and off-design blade element performance of, and flow through a double-circular-arc (DCA) compressor cascade is being examined in a large subsonic cascade wind tunnel.

Tests are to be made subsequently of a controlled-diffusion (CD) cascade configuration designed to replace it as the midspan section of the stator of an axial transonic compressor.

Previous phases of the work involving tests with the present DCA blading were reported by Cina [Ref. 1] and Molloy [Ref. 2]. Cina's test results were considered to be preliminary because the cascade flow was found not to be periodic from one blade passage to the next, but was periodic from blade pair to blade pair. As a result of Cina's work, a modification to the inlet guide vane (IGV) assembly was made, decreasing the space between vanes from 2 inches to 1 inch. Molloy set out to repeat Cina's experiments, but encountered IGV blade flutter (which resulted in some blade damage) when adjusting the vanes with the cascade running. Facility modifications were made which included first the installation of plenum chamber turning vanes. This reduced the large scale flow fluctuations which had prevented the use of tufts to determine the cause of the flutter problem. Also, the vane actuating mechanism was stiffened and new cascade operating procedures were adopted. Following these improvements,

THE TANK AND THE PARTY OF THE P

the immediate test objective was to document flow quality and the performance of the reference DCA cascade. Addea features of the test program were to investigate the possible effects of Reynolds number and to determine the degree of repeatability of test data from run to run and also from cascade build to build. Additionally, an improvement of the analysis required to derive blade force coefficients from probe survey data was attempted. In the absence of wall suction, side wall boundary layer thickening from inlet to outlet measurement planes causes the control volume to take on a three-dimensional character. An attempt was made to account for the additional pressure-area terms on the control volume surfaces which accompany the streamtube contraction by using the Axial Velocity Density Ratio (AVDR) and an assumed linear distribution of static pressure acting on the streamtube walls. Details of this analysis are presented in Appendix C.

The following report documents a program of 20 tests carried out using the DCA cascade following the facility improvements. Results are given and are discussed, particularly from the viewpoint of flow quality and test repeatability. Details of the results are summarized in figures, tables and appendices. Appendix A contains flow quality documentation, Appendix B, a description of experimental data storage and Appendix C, a discussion of blade force coefficient analysis.

#### II. TEST FACILITY

#### A. HIGH REYNOLDS NUMBER CASCADE

#### 1. Wind Tunnel

A schematic of the test facility as originally configured is shown in Fig. 1. A complete description is given in [Ref. 3].

### 2. Plenum Modifications

The plenum chamber (located in the basement of the cascade building) has undergone successive modifications to provide acceptably uniform inlet conditions measured at the inlet guide vane station. Modifications conducted by Bartocci [Ref. 4] and Moebius [Ref. 5] were superfeded by those of McGuire [Ref. 6]. McGuire's modification to the plenum is illustrated in Fig. 2. McGuire's plenum modification was in place for all tests reported herein.

#### 3. Cascade North Wall Composition

A plexiglass north wall used during cascade tests enabled McGuire to conduct a concurrent flow visualization experiment. The regular steel wall was used for two of the twenty test runs.

# 4. Inlet Guide Vane Assembly

PROPERTY OF THE PROPERTY OF TH

The inlet guide vane assembly was the same as that used by Molloy, with vanes at one inch spacing.

#### 5. Test Section

Views of the cascade test section are shown in Fig. 3a, Fig. 3b, and Fig. 4. Fig. 3a shows the cascade test section with the plexiglass wall installed and the DCA blade row in place. Fig. 3b shows the test section with the steel wall in place. Fig. 4 illustrates instrumentation placement and physical dimensions.

#### B. INSTRUMENTATION

# Survey Probes

Two United Sensor Corporation five-hole probes were used for surveys at the upper and lower planes. A DC-125-24-F-22-CD probe, serial number A981-2 was used at the upper plane and a DA-125 probe, serial A847-1 was used at the lower plane.

#### 2. Reference Probes

Plenum chamber reference total pressure was sensed using a pressure tube suspended in the plenum. Reference static pressure was sensed using a static port located on the lower portion of the cascade south wall. Redundancy of reference pressures was provided by a standard pitot-static probe located approximately 2 inches from the entrance to the blade row at midspan and aligned with the inlet flow.

#### Wall Pressure Taps

RECEIPE TO SELECTION OF THE PROPERTY OF THE PR

Two rows of static pressure taps were located on the cascade south wall 16.25 inches ahead and 6.5 inches

behind mid-chord. Twenty taps per row spaced two inches apart in the blade-to-blade direction, each connected to a water manometer board, allowed visual inspection of the inlet and outlet static pressure distributions.

#### 4. Acquisition and Reduction System

Data was acquired, reduced and plotted using a modified Hewlett Packard HP-3052A Data Acquisition System [Ref. 7]. Two 48-port Scanivalves connected to a HP-9845A desktop computer via a NPS/TPL HG-78K Scanivalve Controller and a HP-98034A HP-IB Interface Bus allowed all probe and reference pressures to use a single transducer. Blade surface pressures were sensed by the second Scanivalve transducer. The desktop computer acted as the system controller and used acquisition, reduction and plotting software programs documented in [Ref. 8].

## 5. Measurement Uncertainty

TOTAL PROPERTY PERSONNEL PROPERTY (PROPERTY AND PROPERTY OF

Table I summarizes measurement uncertainties.

#### III. EXPERIMENTAL PROCEDURES

#### A. GENERAL

#### 1. Flow Quality

Flow uniformity, periodicity, and pseudo two-dimensionality criteria (which implies that area change is permitted) must be satisfied before any calculated cascade performance parameters can be considered meaningful. These flow quality criteria are discussed extensively in [Ref. 9], [Ref. 10] and [Ref. 11].

Uniformity generally describes the degree of constancy of measured values in the blade-to-blade and spanwise directions at the inlet plane and in the spanwise direction at the outlet plane. Periodicity is indicated by a correspondence of measured values from one blade space to the next at the outlet plane. The pseudo two-dimensionality condition is met when the integrated blade surface pressure distribution gives a blade force vector coincident with the blade force vector calculated using the principle of conservation of momentum.

#### 2. Flow Geometry

Definition of geometrical parameters describing flow through a cascade are given in Fig. 5. Angle measurements were taken from a vertical reference line, clockwise being positive.

#### 3. Reference Quantities

To remove time dependency of inlet dynamic pressure caused by atmospheric fluctuations and variations in blower speed, each pressure measurement was referenced to plenum conditions, a procedure validated earlier by Duval [Ref. 11].

#### 4. Performance Parameters

Cascade performance parameters were calculated using the formulas listed in Table II. Note that the effect of AVDR on loss coefficient, static pressure rise coefficient, diffusion factor and blade force coefficient derived from momentum conservation was accounted for in each expression.

#### B. SPECIFIC TEST PROCEDURES

#### Probe Calibration

Constitution of the Consti

Prior to testing, both United Sensor five-hole probes were calibrated in a free jet flow. The calibration was represented using Zebner's analytical procedure [Ref. 12] and computer software developed by Neuhoff [Ref. 13].

# Test Section Setup and Adjustment

Tests were conducted at constant stagger angle while varying only air inlet angle and velocity magnitude. To set an inlet condition, before starting the cascade the lower end walls were set to the desired inlet air angle with end wall spacings set to 1.5 inches (one-half blade space). The IGVs were set to deliver the desired inlet air angle following a schedule established in preliminary tests conducted

without test blades. Finally, upper end walls were positioned approximately. The cascade was started and the upper end wall angles were fine-tuned to give a uniform static pressure distribution at the outlet plane. A check of the inlet air angle was made with the lower probe placed at midspan in the center of the blade-to-blade traverse. If adjustment of the IGVs was required, the cascade was first shut down, the IGVs were readjusted, the cascade was restarted and the inlet air angle was checked again after the cascade had stabilized at the inlet dynamic pressure required for the test. 1

#### 3. Test Measurements

#### a. Blade-to-Blade Survey

Blade-to-blade surveys were conducted using the upper and lower probes simultaneously. Both probes were located at midspan with the lower probe trailing the upper by two inches. Measurements were recorded over four adjacent blade spaces located in the center portion of the cascade test section. The two innermost blade spaces bracketed the center blade which was instrumented with 39 pressure taps. Survey points were spaced 0.25 inches apart over the outermost spaces and at 0.125 inches over the two innermost spaces.

Inlet guide vane flutter similar to that reported by Molloy [Ref. 2] reoccurred while adjusting the IGV assembly at relatively high inlet dynamic pressure (about 17 inches of water). Thus it is essential not to adjust the inlet guide vanes while the cascade is operating.

Closely spaced survey points over two blade passages insured that one full blade wake would be surveyed with good spatial resolution.

#### b. Spanwise Survey

Two spanwise surveys were carried out to establish the spanwise extent of uniform conditions. First, measurements were taken with the upper probe 1 inch from the suction side of the centermost blade and the lower probe 1 inch from the pressure side of the centermost blade. Once the first spanwise traverse was complete, the upper probe was placed 1 inch from the pressure side, the lower placed 1 inch from the suction side and the spanwise traverse was repeated.

#### c. Instrumented Blade Pressure Distribution

After completing the blade-to-blade and spanwise traverse, one or more sets of blade pressure distribution data were recorded.

#### IV. TEST CASCADE AND PROGRAM OF TESTS

#### A. CASCADE CONFIGURATION

Constant parameters for the cascade configuration are summarized in Table III.

#### 1. Blading

section double circular arc (DCA) blades of aspect ratio
2.0 and chord 5.01 inches. Coordinates for the test blades
are given in Table IV. Three of the twenty blades were instrumented with static pressure taps at midspan in order
to provide measurements of blade static pressure distribution.
The center blade contained 39 pressure taps while each adjacent blade had 6 taps. Adjacent blade instrumentation provided a measure of the uniformity of pressure distribution
from one blade to the next. Pressure tap locations for the
center instrumented blade are illustrated in Fig. 6. Fig. 7
shows a photo of the center instrumented blade.

#### B. TEST PARAMETERS

The results of 20 tests are reported for which the test parameters are summarized in Table V.

#### 1. Incidence Angle

Seven test values of incidence angle were chosen.

Five of the seven angles were approximately those reported

by Cina to allow a comparison to be made of corresponding data sets.

## 2. Reynolds Number

In order to investigate the possible dependence of cascade flow quality and performance on Reynolds number, each incidence angle was tested at at least two Reynolds numbers. The Reynolds number based on chord was varied between 491,000 and 773,000.

#### V. RESULTS

#### A. FLOW QUALITY

Uniformity, periodicity and pseudo two-dimensionality were evaluated from data presented in Appendix A and are summarized in Tables VI and VII.

#### B. CASCADE PERFORMANCE

Cascade performance is summarized in Figs. 8 through 13 and in Table VIII.

#### C. TEST REPEATABILITY

and distincted actions substitute, preparately solubles ensured therewere, appropriately decided by

Run-to-run repeatability of cascade performance parameters is indicated in Figs. 8 to 13 by double-headed solid arrows. The arrow indicates the observed range of the applicable cascade performance parameter. Tunnel build-to-build repeatability was investigated at the design incidence angle of 2.2 degrees. Double-headed broken arrows indicate build-to-build repeatability.

#### VI. DISCUSSION

#### A. FLOW QUALITY

CONTRACTOR CONTRACTOR STREET

CHESTANDS CHEROSCON (PROPERTY PROPERTY CONTRACTOR CONTRACTOR

#### 1. Uniformity

As seen in Table VI, the dynamic pressure, static pressure, total pressure and non-dimensional velocity were acceptably uniform over at least twenty percent of blade span at the inlet and outlet planes, and over the entire twelve inch blade-to-blade traverse at the inlet plane.

Inlet and outlet air angle were acceptably uniform in the spanwise direction. Beta 1 was indicated to vary slightly in the blade-to-blade direction. The average total change in Beta 1 from beginning to end of a 12 inch blade-to-blade traverse was approximately one degree. Since adjustment of the inlet guide vane assembly with the cascade running was prohibited, this variation was accepted. If the IGV mechanism was stiffened further to allow adjustment during cascade operation, strict uniformity of inlet air angle would probably be assured.

# 2. Periodicity

With the exception of the most negative incidence angle of -12.5 degrees, good periodicity was obtained over the three centermost blades. Surface pressures from the left, center and right blades were in excellent agreement except at i = -12.5 degrees. Also, all flow parameters

measured at the outlet plane at midspan were closely periodic from one blade space to the next with the exception of the most negative incidence angle.

#### 3. Pseudo Two-Dimensionality

THE PARTY OF THE PROPERTY OF THE PARTY OF TH

Despite the revision which was made to the calculation of C<sub>fM</sub>, (the blade force coefficient derived from probe survey data; Appendix C), agreement between  $C_{fM}$  and  $C_{fB}$ , (the blade force coefficient derived from surface pressure measurements), was achieved in only about 50 percent of the tests (Table VII). The problem is thought to lie in the calculation of the axial component of  $C_{fM}^{\cdot}$ . An order of magnitude comparison of the terms that make up the axial component C<sub>fM</sub> (Eqn. C. 14) revealed that the first two terms were of order 1.0, the third and fourth terms of order 10.0, and the fifth term of order The difference between the first two pairs of terms, however, were both less than order 1.0, with the pressurearea integrals contributing the most. Thus, the value of  $C_{\text{fM}}$  was highly sensitive to small inaccuracies in the survey data and too coarse spacing of data points. The more satisfactory results obtained for the tangential components of  $C_{fM}$  can be explained because its evaluation does not involve pressure-area integration terms.

# 4. Effect of North Wall Composition

At one incidence angle the more rigid and slightly better-fitting steel wall was used. The resultant spanwise distribution of flow parameters was generally indistinguishable

from the distributions obtained when using the plexiglass wall. (See Figs. A.51 to A.76 and Figs. A.139 to A.144).

#### B. CASCADE PERFORMANCE

#### 1. Effect of Reynolds Number

Figs. 8 to 13, and Appendix A show that varying Reynolds number from approximately 500,000 to 770,000 had no measurable effect on the blading performance or on the cascade flow quality. This can probably be explained as being due to the controlling influence of a leading edge separation bubble on the suction side boundary layer transition [Ref. 6]. Conducting tests significantly above a prescribed threshold Reynolds number is therefore unnecessary for this blade set. It is noted that when operating at Reynolds numbers of 500,000, adjustment of the IGV assembly with the cascade running may be possible in the future after further stiffening of the actuating mechanism.

#### C. TEST REPEATABILITY

Run-to-run repeatability of cascade performance parameters was satisfactory as was build-to-build repeatability. The total uncertainties in the measurements of AVDR, loss coefficient, deviation angle and static pressure rise coefficient were about 0.01, 0.005, 0.4 degree, and 0.02 respectively.

#### D. COMPARISON WITH CINA

Figs. 8 through 13 each contain a broken line showing the results of Cina's DCA cascade tests. Differences between the two data sets are apparent. Given a specific incidence angle, Cina reported a lower loss coefficient, deviation angle and AVDR, and higher static pressure rise coefficient. Three contributing factors can be cited. First, and most importantly, Cina operated with a different IGV assembly that did not deliver periodic conditions bladepassage to blade-passage. Secondly, he used a plenum which gave less stable, more turbulent supply conditions. Finally, the upper and lower traverse probes were carefully recalibrated after Cina completed his tests.

#### VII. CONCLUSIONS

Based on an examination of experimental data the following conclusions are drawn.

- 1. The cascade flow was satisfactorily uniform.
  Uniformity existed at the upper and lower planes over at
  least 20% of blade span near midspan and at the lower plane
  (midspan) in the blade-to-blade direction for all measured
  flow parameters at all tested inlet conditions.
- 2. The cascade flow was satisfactorily periodic.

  Periodicity existed at the upper plane (midspan) in the blade-to-blade direction for all inlet conditions tested.
- 3. The cascade flow was not shown consistently to be strictly pseudo two-dimensional. Accounting for streamtube contraction due to side wall boundary layer thickening from lower to upper measuring planes introduced additional small terms into the equation for the axial force component. However, the calculation of the axial force is dominated by the difference between two pressure-area integrals of much greater magnitude.
- 4. Cascade performance parameters were not measurably affected by varying Reynolds number in the range 500,000 to 770,000.
- 5. Test conditions can be repeated within an acceptable uncertainty from run-to-run. Build-to-build conditions can

also be successfully repeated.

- 6. Use of the plexiglass north wall instead of a steel wall had no measurable effect on the results.
- 7. Inlet guide vanes cannot be safely adjusted with the cascade operating.

#### VIII. RECOMMENDATIONS

It is recommended that the following actions be considered.

- 1. The inlet guide vane assembly should be modified to allow adjustment of the IGVs while the cascade is running.
- 2. Yaw balancing manometers should be inclined in order to provide the experimenter with better inlet and outlet air angle measurement sensitivity.
- 3. The motor driven yaw and spanwise positioning systems mounted on the upper traverse caused a significant bending moment to be placed on the probe blade-to-blade slide. Noticeable wear of the upper traverse mechanism took place during the course of twenty test runs. Removal of the power yaw and span drives in favor of a lighter-weight mount similar to that at the lower plane is recommended.
- 4. Provide ready data file transfer from the HP-9845A cassette tapes to the IBM 3033 computer so that advantage can be taken of the DISSPLA graphics capability available at the NPS Computer Center.

#### APPENDIX A

#### A. FLOW QUALITY DOCUMENTATION

## 1. Uniformity

Uniformity of dynamic pressure  $(Q/\bar{Q})$ , static pressure  $(\Delta Ps/\bar{Q})$ , total pressure  $(\Delta Pt/\bar{Q})$ , non dimensional velocity  $(X/\bar{X})$ , and Beta for spanwise surveys at the inlet and outlet planes and blade-to-blade surveys at the inlet plane at each test condition are shown in Figs. A.1 through A.105. Photographs of upper and lower static pressure distributions for each incidence angle and Reynolds number comprise Figs. A.106 to A.119.

#### 2. Periodicity

Periodicity of  $(Q/\bar{Q})$ ,  $(\Delta Ps/\bar{Q})$ ,  $(\Delta Pt/\bar{Q})$ ,  $(X/\bar{X})$  and Beta for blade-to-blade surveys at the outlet plane and adjacent blade pressure distribution for each test condition are shown in Figs. A.120 through A.168.

### 3. Pseudo Two-Dimensionality

Blade force coefficients for each test condition are plotted in Figs. A.169 to A.182.

#### 4. Notation

The parameters plotted in Figs. A.1 to A.105 and Figs. A.122 to A.154 are defined as follows:

Parameter	Meaning
Q/Q	local value of $Q/\overline{Q}^2$
$\Delta Ps/\bar{Q}$	(P <sub>s</sub> - P <sub>wl</sub> )/Q
ΔPt/Q	$(P_{plen} - P_{t})/\bar{Q}$
x/x̄	local value of $X/\bar{X}$

actal resolution legislar besidest, regisler booksame acceptan bellight acceptant analysist resolution bes

<sup>&</sup>lt;sup>2</sup>"Barred" quantities apply to the specific measurement plane and are calculated over a prescribed integration interval—usually one blade space.

### APPENDIX B

#### A. STORAGE OF EXPERIMENTAL DATA

# 1. Storage Devices

#### a. Cassette Tape

All raw and reduced data acquired during the current study via the HP-3052A acquisition system were stored on cassette tape. Table B.1 summarizes the raw data filenames according to inlet air angle and cassette tape number. Tapes were filed with the Director, Turbopropulsion Laboratory, Naval Postgraduate School, Monterey, Ca.

### b. File Naming Scheme

All files were named using a six character alphanumeric code that allowed the investigator to immediately identify stored data in any file and on what date it was recorded. Here is how the code works.

1st character: Indicates the type of traverse conducted ("B"lade-to blade, "S"panwise or "I"nstrumented blade data).

2nd character: Indicates the "state" of the data set (ra"W", re"D"uced or "F"inal).

3rd character: Indicates which probe was involved in taking the data set, either "U"pper or "L"ower. No letter here means that the probes acquired data simultaneously.

4th, 5th and 6th characters: These numbers indicate the julian date in 1983 that the test run was conducted.

For example, a file containing data from a raw blade-to-blade survey using the upper probe conducted on January 15, 1983 would be named BWU015. When upper and lower probes were traversed together the "U"pper or "L"ower character was dropped and the entire julian date filled the remaining four spaces. For example, if the upper and lower probes were both traversed in the blade-to-blade direction on January 15, 1983, the resultant raw data filename would be named BW3015.

CHAPTER TO THE CONTRACTOR

SECTION CONTRACTOR CONTRACTOR CONTRACTOR

THE PROPERTY OF THE PROPERTY O

Sometimes, in order to completely describe a reduced data file, parts of the julian date had to be sacrificed. Raw data from a spanwise survey of the upper probe one inch from the suction side of the centermost instrumented blade conducted on February 1, 1983 would be named SWSU32 ("S"panwise, ra"W", 1 inch from "S"uction side, "U"pper probe, julian date 30"32"). It should be noted that when spanwise surveys were conducted, both probes moved together. To preclude interference of the lower probe wake with the upper probe measurements, the upper probe was place 1 inch from the suction side, and the lower probe was placed 1 inch from the pressure side of the center blade. The composite data file was named with the upper probe in mind, however, even though the lower probe was stationed at a different bladeto-blade position. For example, a raw spanwise survey named SWS077 would show that the upper probe was 1 inch from the

suction side of the center blade, while the lower probe was l inch from the pressure side.

Some specialized filenames reflect the type of data stored. Referencing constants calculated for a test conducted on February 15, 1983 would be named RC046A or RC046B where the "A" would mean that the referencing constants were calculated using the plenum total pressure and the lower wall static pressure as reference total and static pressures. "B" would indicate that the reference total and static pressures sures were supplied by the pitot-static probe.

# 2. Thesis Logbook

A chronological log of the present study with notes and printouts of all data files was deposited with the Director, Turbopropulsion Laboratory.

#### B. PROBE CALIBRATION DATA

A folder documenting the calibration of United Sensor probes serial number 847-1 and 981-2 was filed with the Laboratory Manager, Turbopropulsion Laboratory. Non-dimensional velocity (X) and pitch angle (PHI) calibration files for both probes appear on each data storage cassette tape. Their names reflect the file type and the applicable probe. For example, the pitch angle calibration file for the 981 probe is named "PHI981", the X velocity calibration file for the 847 probe is named "X847", and so on.

### APPENDIX C

EFFECT OF AVDR ON THE AXIAL FORCE COEFFICIENT DERIVED FROM PROBE SURVEY DATA.

The notation used in this section follows [Ref. 14] and [Ref. 15]. The application of the principle of momentum conservation to the control volume shown in Fig. C.1 results in the following expression for the resultant force on the control volume;

$$\vec{R}_{w} = \int_{S_{1}} \vec{V}_{1} d\dot{m}_{1} - \int_{S_{2}} \vec{V}_{2} d\dot{m}_{2} + \int_{S_{1}} d\vec{F}_{1} + \int_{S_{2}} d\vec{F}_{2} + \int_{\mathbf{B}} d\vec{F}_{a} + \int_{\mathbf{B}} d\vec{F}_{b}$$

A SERVED APPEARING TO SERVED A TO SERVED AND THE

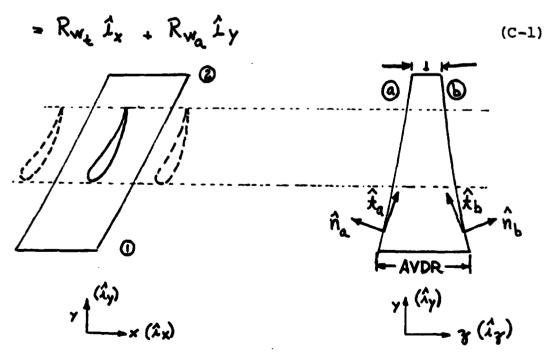

Figure C.1. Blade Space Control Volume

In the enlarged view of the edge of curved surface a, the unit outward normal vector,  $\hat{\mathbf{n}}_{\mathbf{a}}$  , is given by the relation

$$\hat{n}_a = \cos \alpha \hat{\lambda} y - \sin \alpha \hat{\lambda} y$$
(C-2)

and similarly, on surface b,  $\hat{n}_{b}$  is given by

$$\hat{n}_b = \cos \alpha \hat{n}_y + \sin \alpha \hat{n}_y$$
(C-3)

The elemental area "s" on the curved sidewall of the control volume can be expressed as the projection of an element of the base area dS, where

$$dS = dx dy$$
 (C-4)

so that,

$$ds = \frac{dx \, dy}{\cos \alpha} \tag{C-5}$$

Resolving the elemental force,  $d\bar{\textbf{F}}$  , acting on the curved sidewalls of the control volume into normal and sheer components gives

$$d\vec{F} = -p\hat{n}ds - \tau \hat{z}ds \qquad (C-6)$$

Neglecting wall friction,  $\tau$  , the tangential force becomes:

$$R_{W_{e}} = \int_{S_{1}} g_{1} V_{u_{1}} dA_{1} - \int_{S_{2}} g_{2} V_{u_{2}} dA_{2}$$
(C-7)

and the axial force becomes:

$$R_{w_{a}} = \int_{S_{1}} P_{1} V_{a_{1}}^{2} dA_{1} - \int_{S_{2}} P_{2} V_{a_{2}}^{2} dA_{2} + \int_{S_{1}} P_{1} dA_{1}$$

$$- \int_{S_{2}} P_{2} dA_{2} + \int_{a} \lambda_{y} \cdot d\vec{F}_{a} + \int_{b} \lambda_{y} \cdot d\vec{F}_{b}$$
(C-8)

Using Eq. 
$$(C-2)$$
, Eq.  $(C-3)$ , Eq.  $(C-5)$  and Eq.  $(C-6)$ ,

$$\int_{a} \hat{x}_{y} \cdot d\vec{F}_{a} = \int_{a} \hat{x}_{y} \left[ -p(\cos \alpha \cdot \hat{x}_{y} - \sin \alpha \hat{x}_{y}) \right] \frac{dx dy}{\cos \alpha}$$

$$= \int_{a} -p dx dy$$
(C-9)

and similarly,

$$\int_{b} \hat{\lambda}_{y} \cdot d\vec{F}_{b} = \int_{b} -p dx dy$$
(c-10)

which represent additional axial force components due to pressure forces on the control volume side walls.

$$R_{wa} = \int_{P_{1}}^{S_{1}} V_{a_{1}}^{2} (AVDR) dx - \int_{P_{2}}^{S_{2}} V_{a_{2}}^{2} dx + \int_{P_{1}}^{S_{1}} (AVDR) dx - \int_{P_{2}}^{S_{2}} dx - 2 \int_{P_{1}}^{P_{2}} (AVDR) dx dx$$
(C-11)

which contains a fifth axial force term not included by Cina, and a modification of the first and third terms resulting from the effects of AVDR.

Since the precise function p(y) is not known from station 1 to station 2, a linear change of pressure with y was assumed as depicted in Fig. C.2.

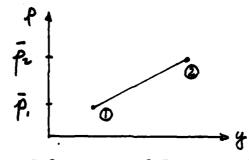

Figure C.2. Assumed Pressure Function

The fifth term of Eq. (C-11) can then be approximated as:  $-2\int_{a} p(y) dy dx = -5\left\{ \vec{p} \left( AVDR-1 \right) + \left[ \left( \frac{\vec{p}_{1}}{2} - \vec{p}_{1} \right) \right] \left[ AVDR-1 \right] \right\}_{(C-12)}$ 

Assuming that
$$\vec{p}_i \cdot S \cdot AVDR = \int_0^s \vec{p}_i \cdot AVDR \cdot dx$$
(C-13)

substitution of Eq. (C-13) and Eq. (C-12) into Eq. (C-11)

yields,  

$$R_{w_{a}} = \int_{0}^{S} P_{1} V_{a_{1}}^{2} (AVDR) dx - \int_{0}^{S} P_{2} V_{a_{2}}^{2} dx + \int_{0}^{S} P_{1} dx$$

$$- \int_{0}^{S} P_{2} dx - \left[ \left( \frac{\bar{P}_{2} - \bar{P}_{1}}{2} \right) \left[ AVDR - I \right] S \right]$$
(C-14)

Equation (C-14) was reduced to force coefficient form using procedures explained in [Ref. 1] and then incorporated into existing software documented in [Ref. 8].
